

Worst User Interface I Have Used

The worst user interface I have experienced is the old railway ticket booking website for Bangladesh Railway. It was poorly designed, confusing, and slow. The layout used inconsistent fonts and small text that was difficult to read on both desktop and mobile devices. Dropdown menus overlapped with other content, and buttons were placed in unpredictable positions.

One major issue was the lack of real-time feedback. After clicking "Search Trains," there was no loading indicator, leaving users unsure if their request was being processed. The color scheme used red text on dark backgrounds, which reduced readability. Error messages were vague, often saying only "Invalid Input" without clarifying what went wrong.

To improve the system, the developers could use a modern grid layout, clear typography, and consistent color contrast. Implementing proper form validation and real-time feedback would also greatly enhance the experience. A responsive design would make the website more usable on phones and tablets, which most users rely on.

I believe the poor design resulted from outdated technology and a lack of user testing. The developers likely focused on backend functionality rather than usability. This interface demonstrates how ignoring basic UX principles can turn a necessary service into a frustrating experience.
